BST Construction from Given Elements

Problem Statement

Write a C++ program to construct a Binary Search Tree (BST) using the elements **14, 15, 4, 9, 7, 18, 3, and 5** in the given order. Display the tree after each insertion so that the changes to the BST can be observed. After inserting all elements, display the Inorder, Preorder, and Postorder depth-first traversals of the final tree. Calculate and display the height of the final BST and the total number of leaf nodes. Finally, allow the user to enter a value to search for in the BST and report whether it is found. Allow the user to enter a value to delete, delete that node while preserving the Binary Search Tree property, and display the updated tree after deletion.
